Abstract

Objectives. To investigate the dynamics of response of synovitis to interleukin (IL)-17A inhibition with secukinumab in patients with active psoriatic arthritis (PsA) using Power Doppler ultrasound.

Methods. The randomised, placebo-controlled, Phase III ULTIMATE study enrolled PsA patients with active ultrasound synovitis, and clinical synovitis and enthesitis having an inadequate response to conventional disease-modifying anti-rheumatic drugs (DMARDs) and naïve to biologic DMARDs. Patients were randomly assigned to receive either weekly subcutaneous secukinumab (300 or 150 mg according to the severity of psoriasis) or placebo followed by 4-weekly dosing thereafter. The primary outcome was the mean change in the ultrasound Global European League Against Rheumatism and Outcome Measures in Rheumatoid Arthritis Clinical Trials Synovitis Score (GLOESS) from baseline to Week 12. Key secondary endpoints included American College of Rheumatology 20 and 50 responses.

Results: Of the 166 patients enrolled, 97% completed 12 weeks of treatment (secukinumab, 99%; placebo, 95%). The primary endpoint was met, and the adjusted mean change in GLOESS was higher with secukinumab than placebo (-9 [0.9] vs -6 [0.9], difference [95% CI]: -3 [-6 ; -1]; one-sided $P=0.004$) at Week 12. The difference in GLOESS between secukinumab and placebo was significant as early as one week after initiation of treatment. All key secondary endpoints were met. No new or unexpected safety findings were reported.

1
2
3 **Conclusion:** This unique ultrasound study shows that apart from improving the
4 signs and symptoms of PsA, IL-17A inhibition with secukinumab leads to a rapid
5 and significant reduction of synovitis in PsA patients.

Introduction

Psoriatic arthritis (PsA) is characterised by inflammation of synovial membranes and enthesal sites leading to pain, structural damage, impairment of physical function and quality of life [1–5]. Abrogation of inflammation in the joints is a central goal for the treatment of PsA, like in any other form of inflammatory arthritis. However, to date the effects of drug therapy on disease are usually measured indirectly, through assessing the impact on signs and symptoms of disease, rather than directly assessing inflammation at joint level. Hence, little is known about the dynamic effect of disease modifying anti-rheumatic drugs (DMARDs) on synovitis.

Ultrasound in B-mode combined with Power Doppler (PD; the association named PDUS), permits visualisation of both morphological and functional changes of synovium [6, 7]. The European League Against Rheumatism (EULAR) and the Outcome Measures in Rheumatoid Arthritis Clinical Trials (OMERACT) have recently standardised the use of PDUS for detecting synovitis and developed a composite scoring system at joint and patient level: the Global EULAR-OMERACT Synovitis Score (GLOESS), which has shown high responsiveness to treatment and excellent reliability in rheumatoid arthritis (RA) patients [8–11], suggesting the possibility to be used to monitor treatment response in inflammatory arthritis.

Secukinumab, a human monoclonal antibody that directly inhibits interleukin (IL)-17A, has demonstrated sustained efficacy on signs and symptoms, inhibition of structural damage progression, and a favourable long-term safety profile in patients with PsA over 5 years [12–14], however, little is known on its direct effect on synovitis (and enthesitis) and the dynamics of such response. To investigate this, we initiated the

1
2
3 ULTIMATE study, which is the first PDUS-based randomised placebo-controlled trial in
4
5 PsA that primarily focussed on synovial responses rather than on signs and symptoms
6
7 of disease. Hence, the primary aim of the ULTIMATE study was to evaluate whether
8
9 treatment with secukinumab inhibits synovitis, as measured by PDUS, in patients with
10
11 active PsA who failed conventional synthetic DMARDs (csDMARDs) therapy and were
12
13 naïve to biological DMARDs (bDMARDs). Herein, we present the primary efficacy data
14
15
16 of secukinumab on synovitis in patients with active PsA.
17
18
19
20

21 **Methods**

22 **Patients and study design**

23
24
25 Biologic-naïve patients (aged ≥ 18 years) with a diagnosis of PsA for at least 6 months,
26
27 fulfilling the CASPAR criteria, and having an inadequate response to csDMARDs and
28
29 an active disease based on tender joint count (TJC) ≥ 3 of 78 joints and swollen joint
30
31 count (SJC) ≥ 3 of 76 joints were considered eligible for this study. In addition, patients
32
33 had to present active PDUS synovitis according to a pre-defined cut-off (Supplementary
34
35 Figure S1 and Table S1, available at *Rheumatology* online) at screening and baseline
36
37 and at least one clinical enthesitis at screening and baseline. Patients could continue to
38
39 receive methotrexate, glucocorticoids, and nonsteroidal anti-inflammatory drugs
40
41 (NSAIDs) at a stable standard dose from 1-month prior to screening to 24 weeks
42
43 (Supplementary Figure S2, available at *Rheumatology* online).
44
45
46
47
48
49

50 Key exclusion criteria included evidence of an ongoing infection or malignant
51
52 process; prior treatment with bDMARDs, including tumor necrosis factor inhibitors;
53
54 active ongoing inflammatory conditions other than PsA; active systemic infection within
55
56
57
58
59
60

Secukinumab in PsA: PDUS assessment

1
2
3 2 weeks before randomisation; history of ongoing, chronic, or recurrent infectious
4
5 disease or evidence of tuberculosis infection; known infection with human
6
7 immunodeficiency virus or hepatitis B or C at screening or randomisation; and history of
8
9 lymphoproliferative disease, any known malignancy, or malignancy of any organ system
10
11 within the past 5 years. Detailed inclusion and exclusion criteria are listed in the
12
13 Supplementary Table S1, available at *Rheumatology* online.
14
15

16
17 ULTIMATE (NCT02662985) was a multicentre, randomised, double-blind,
18
19 placebo-controlled, 52-week Phase III study (Supplementary Figure S2, available at
20
21 *Rheumatology* online). The study was initiated on August 22, 2016 (first patient, first
22
23 visit), and conducted across 37 active sites in 17 countries. This study consisted of a 1-
24
25 to 4-week screening phase, followed by a 12-week, double-blind, placebo-controlled
26
27 treatment period (TP 1; baseline to Week 12); a 12-week open-label period (TP 2; Week
28
29 12 to Week 24); a 6-month, open-label extension period (TP 3; Week 24 to Week 52);
30
31 and a 12-week safety follow-up period (Week 52 to Week 64; Supplementary Figure S2,
32
33 available at *Rheumatology* online).
34
35
36

37
38 Enrolled patients were randomised (1:1) using Interactive Response Technology
39
40 (IRT) to receive either subcutaneous secukinumab (300 mg or 150 mg) or placebo
41
42 weekly followed by 4-weekly dosing at Weeks 4 and 8 in a double-blind manner
43
44 (Supplementary Figure S2, available at *Rheumatology* online). Patients received
45
46 secukinumab 300 mg or 150 mg according to the severity of skin disease. The open-
47
48 label phase started at Week 12 (TP 2), and all patients (including the placebo group)
49
50 received secukinumab 300 mg or 150 mg depending on the skin severity through IRT
51
52 every 4 weeks until Week 52 in an open-label manner. Patients, study centre personnel
53
54
55
56
57
58
59
60

1
2
3 (including ultrasound and clinical investigators), and data analysts were fully blinded to
4
5 the treatment assigned to patients at randomisation for the first 12 weeks of the study
6
7 (TP 1). The ultrasound and clinical investigators remained blinded from each other until
8
9 the final database lock.
10

11
12 The study protocol and its amendments were reviewed and approved by the
13
14 independent ethics committee or institutional review board for each participating centre.
15
16 The study was conducted according to the International Council for Harmonisation (ICH)
17
18 E6 Guideline for Good Clinical Practice (GCP) that has its origin in the Declaration of
19
20 Helsinki [15]. Written informed consent was obtained from all enrolled patients. Data
21
22 were collected in accordance with the GCP guidelines by the study investigators and
23
24 analysed by the sponsor.
25
26

27 28 **Assessment of joints by ultrasound** 29

30
31 PDUS evaluation was performed at screening; baseline; and Weeks 1, 2, 4, 6, 8,
32
33 and 12. The following 24 joints were evaluated bilaterally: metacarpophalangeal (MCP)
34
35 joints 1 to 5, proximal interphalangeal (PIP) joints 1 to 5, metatarsophalangeal (MTP)
36
37 joints 1 to 5, distal interphalangeal (DIP) joints 2 to 5, wrists, elbows, shoulders
38
39 (glenohumeral), knees and ankles (tibiotalar). The joints were scanned at each visit
40
41 from the dorsal aspect, with the joint in a neutral position, except for the knee, which
42
43 was examined in a flexed position (30°). All recesses of each joint were scanned, and
44
45 the detection of maximal grading of PDUS synovitis in one of these recesses
46
47 determined the final grade of the joint.
48
49

50
51 All PDUS evaluations were performed at each site by an independent examiner,
52
53 expert in musculoskeletal ultrasound, with more than 5 years of experience, and blinded
54
55
56
57
58
59
60

Secukinumab in PsA: PDUS assessment

1
2
3 to the clinical evaluation. To ensure homogeneity of PDUS synovitis scoring, all
4
5 ultrasound investigators completed an extensive 2-day training session, including
6
7 examination of patients with PsA. In addition, ultrasound settings were not changed
8
9 during the study, standardised joint and probe positions were used, and software was
10
11 not upgraded. Centres were advised to create a fixed study setting to be used at each
12
13 evaluation.
14
15

16
17 Medium- to high-level ultrasound machines (ESAOTE, Acuson, Logic Series 9, 7
18
19 and enext GE, Siemens or other, such as Toshiba Xario 200, Toshiba Aplio [300, 400],
20
21 Aloka Arietta V70, and Samsung HS60) were used, which employed high frequency
22
23 (12–18 MHz) transducers. Doppler parameters were adjusted according to the device
24
25 used (range of pulse repetition frequency 400–800 Hz; Doppler frequency 7–14.1 MHz).
26
27

28
29 PDUS synovitis was defined according to the EULAR-OMERACT definition as a
30
31 hypoechoic synovial hypertrophy (SH) detected in B-mode, which may show PD signal.
32
33 At each visit, PDUS synovitis was graded semi-quantitatively (0 to 3) according to the
34
35 EULAR-OMERACT PDUS composite score (Table 1) [8, 11]. In addition, single
36
37 components of this composite score (i.e. hypoechoic SH and PD synovial signal) were
38
39 scored separately at each visit.
40
41

42
43 The GLOESS for the 24 paired joints was calculated as the sum of each PDUS
44
45 composite score for all joints examined, giving a potential score ranging from 0 to 144.
46
47 As previously reported, GLOESS incorporates both B-mode and PD measures of
48
49 synovitis and allows to evaluate changes in the activity and morphology of synovitis. To
50
51 help in grading severity, an atlas with examples of B-mode and PD grading for all joints
52
53 examined was available in each centre.
54
55
56
57
58
59
60

1
2
3 All images were recorded, anonymised and sent for central reading for the first
4 patient enrolled at each centre to allow a verification of the consistent scoring across
5 sites. Training session and central reading of the images collected from the first
6 included patient enrolled in each site were considered adequate to ensure a
7 homogeneous rating across sites.
8
9

14 **Clinical and safety assessments**

16 Joints were assessed clinically for tenderness and swelling to calculate the TJC and
17 SJC. In addition, American College of Rheumatology 20, 50, and 70 (ACR20, 50, and
18 70) responses and their core components and the mean change from baseline in Health
19 Assessment Questionnaire Disability Index (HAQ-DI) were evaluated. Safety
20 assessments, including adverse events (AEs), serious AEs, and AEs of special interest
21 occurring during the first 12 weeks, were performed in all patients receiving at least one
22 dose of study drug.
23
24

33 **Statistical analysis**

35 This study was designed to test the superiority of secukinumab compared with placebo
36 at a 5% significance level with a two-sided test. No data applying the EULAR-
37 OMERACT composite PDUS score at the joint or patient level (GLOESS) in PsA were
38 previously reported; however, the mean change from baseline to Week 12 was
39 assumed based on the abatacept treatment effect from a previous PDUS study in RA
40 [16]. Assuming a difference in the mean change from baseline to Week 12 in GLOESS
41 (primary objective) of -6 with a pooled standard deviation of 13.2, a total of 218 patients
42 (109 patients per arm) were estimated to achieve a power of 90%.
43
44

Secukinumab in PsA: PDUS assessment

1
2
3 Blinded sample size re-estimation (SSR) was performed after the completion of
4
5 Week 12 for the first 60 patients and substantiated by data collection from the first 72
6
7 enrolled patients to reassess variability of the disease and adjust sample size
8
9 calculation accordingly. A protocol amendment was introduced to reduce the study
10
11 sample size from 218 patients to 164 patients (82 patients per arm) with the power
12
13 relaxed to 80% and a one-sided ($\alpha=5\%$) superiority test versus placebo for the primary
14
15 objective. The detailed SSR has been provided in Supplementary Table S2, available at
16
17 *Rheumatology* online.
18
19

20
21 The efficacy analyses were performed on the full analysis set, which comprised
22
23 all patients who were randomised and had study treatment assigned. The primary and
24
25 key secondary endpoints were analysed according to a pre-defined statistical hierarchy
26
27 (Supplementary Figure S3, available at *Rheumatology* online). The primary objective
28
29 was to demonstrate a difference in mean change from baseline to Week 12 between
30
31 secukinumab and placebo groups related to PDUS synovitis response using GLOESS
32
33 (sum of the affected joints out of 48 joints). In addition, change between secukinumab
34
35 and placebo from baseline to Week 12 in the core components (SH and PD signal) of
36
37 GLOESS was analysed exploratory. The clinical exploratory outcome measures
38
39 presented here include the proportion of patients achieving ACR70, the mean change
40
41 from baseline in HAQ-DI score, and distribution of joints by ultrasound and clinical
42
43 assessment at baseline.
44
45
46
47
48

49 Data presented for the secukinumab group were pooled data from 300 mg and
50
51 150 mg. The primary analysis was performed using a mixed-effect model repeated
52
53 measures (MMRM; valid under the “missing at random” assumption), with treatment
54
55
56
57
58
59
60

1
2
3 regimen, centre, and analysis visit as factors and weight and baseline GLOESS as
4
5 continuous covariates. Treatment by analysis visit was included as an interaction term
6
7 in the model. An unstructured covariance structure was assumed for this model. The
8
9 significance of the treatment effect for secukinumab was determined using the
10
11 comparisons performed between the secukinumab and placebo arms at Week 12.
12
13 Missing values were imputed as non-response (non-responder imputation [NRI]) for
14
15 binary variables via logistic regression, with study treatment as a factor and baseline
16
17 weight as a covariate. Odds ratio and relative risk (for binary variables) or differences in
18
19 adjusted mean change (for continuous variables) and 95% confidence interval (CI) are
20
21 presented comparing secukinumab versus placebo. A “null zone” derived from the CI
22
23 around the difference, obtained from the MMRM analysis, was plotted for continuous
24
25 variables [17]. It shows the area where the means are located when there is no
26
27 significant difference between the groups at the $P < 0.05$ level.
28
29
30
31
32

33 Safety analyses included all patients who received ≥ 1 dose of study medication.
34
35 AEs were reported as absolute frequencies over the placebo-controlled period, referring
36
37 to the cumulative treatment period (i.e. events started after the first dose of study
38
39 treatment or events present before the first dose of study treatment but increased in
40
41 severity based on preferred term and on or before the last dose plus 84 days). The
42
43 clinical and ultrasound response on enthesitis which were secondary and exploratory
44
45 objectives are not included in the present report.
46
47

Secukinumab in PsA: PDUS assessment

1
2
3 Overall, 258 patients were screened, of whom 82 were ineligible for the study and 10
4 were not included for other reasons (Figure 1). Out of 166 patients (64%) enrolled, 161
5 (97%) completed the first 12 weeks (secukinumab, 99%; placebo, 95%; Figure 1). The
6 proportion of patients with at least one protocol deviation was 15% (secukinumab, 16%;
7 placebo, 13%; Supplementary Table S3, available at *Rheumatology* online).
8
9

10 Demographics and baseline clinical characteristics were comparable between the
11 treatment groups (Table 2). The mean age was 47 years, median disease duration was
12 4 years, and 55% were women. Patients had active disease at baseline with a mean
13 number of 14 tender joints, 9 swollen joints, and 4 clinically active enthesitis, as well as
14 a mean Psoriasis Area and Severity Index score of 10.
15
16

17 The average time spent on PDUS assessments at baseline for the evaluation of
18 the pre-specified set of 24 paired joints was 39 minutes, for both the secukinumab and
19 placebo arms. The distribution of PDUS synovitis revealed that wrists, knees, MCPs,
20 and MTPs were the more frequently affected joints. A similar distribution was observed
21 on clinical examination of swollen or tender joints with lower frequency. These data are
22 presented in a heat map in Figure 2 and Supplementary Figure S4, Tables S4 and S5
23 (available at *Rheumatology* online), respectively.
24
25

26 **PDUS efficacy**

27 The primary endpoint was met at Week 12 (Figure 3); the adjusted mean (SE) change
28 in GLOESS was significantly higher in the secukinumab versus placebo (−9 [0.9] versus
29 −6 [0.9], difference [95% CI]: −3 [−6; −1]; one-sided $P=0.004$). A markedly significant
30 difference between secukinumab and placebo was observed as early as 1-week after
31 treatment initiation. The mean (SE) change from baseline to Week 12 in SH

57
58
59
60

(secukinumab versus placebo) was -9 (0.9) versus -6 (0.9) and in PD was -4 (0.5) versus -2 (0.5), with significance as early as Week 1 for SH and Week 2 for PD signal (Figure 3).

Clinical efficacy

ACR20 and ACR50 responses were met and favored secukinumab-treated patients against placebo at Week 12, with significant improvements observed as early as Week 1 for ACR20 and Week 2 for ACR50 compared with placebo (Figure 4). Significantly higher responses were observed in secukinumab-treated patients for the exploratory endpoints (ACR70 response and HAQ-DI score) at Week 12 compared with placebo (Figure 4). The mean changes from baseline to Week 12 in ACR core components are presented in Supplementary Table S6, available at *Rheumatology* online.

Safety

Overall, the incidence of treatment-emergent AEs up to Week 12 was 58% for the secukinumab group and 57% for the placebo group. The most frequent treatment-emergent AEs in terms of crude incidence rates up to Week 12 were nasopharyngitis, hypertension, diarrhoea, headache, and latent tuberculosis in either secukinumab or placebo group. No serious AEs were reported in the secukinumab group. No deaths, serious infections, neutropaenia, major adverse cardiovascular events, inflammatory bowel disease, or malignancies were reported in either treatment group. Safety data are presented separately for individual treatment groups (secukinumab and placebo) in Supplementary Table S7, available at *Rheumatology* online.

DISCUSSION

Secukinumab in PsA: PDUS assessment

1
2
3 ULTIMATE is the first randomised, placebo-controlled, PDUS Phase III study in PsA
4
5 that primarily aimed to address the effects of biological DMARDs on synovitis detected
6
7 by a validated ultrasound outcome measurement instrument as a primary endpoint. The
8
9 primary efficacy data of the ULTIMATE study showed a significant effect of
10
11 secukinumab treatment compared to placebo in reducing active synovitis in PsA. This
12
13 effect was observed as early as 1-week after the initiation of treatment and continued to
14
15 improve at each time point of evaluation until Week 12. The ultrasound approach also
16
17 allowed assessment of which aspects of synovitis improved first. Thus, the SH
18
19 component showed the response as early as 1-week and the PD component as early as
20
21 2 weeks after treatment initiation, highlighting a fast onset of efficacy of secukinumab in
22
23 controlling inflammation in PsA.
24
25
26
27

28
29 To date, only one small observational study has suggested that DMARDs have
30
31 an effect on synovitis in PsA. [18] Large controlled studies aiming to assess the direct
32
33 effect of DMARDs on synovitis are lacking, despite the availability of objective
34
35 instruments to measure such effects. ULTIMATE study revealed that the activity of
36
37 synovitis in PsA, can be scored at patient level using a validated ultrasound scoring
38
39 system (GLOESS). Moreover, the study showed that reliable assessment of synovitis in
40
41 PsA is feasible across different centres. Thus, GLOESS was sensitive to detect
42
43 decrease in synovitis across different ultrasound devices and examiners even without
44
45 excluding patients with protocol deviations. The absence of a true reliability exercise
46
47 among the examiners may be considered as a limitation. However, potential variability
48
49 in ultrasound assessment related to expertise was minimised using a rigorous
50
51 ultrasound training, an atlas with reference images and central reading of images of the
52
53
54
55
56
57
58
59
60

1
2
3 first patient enrolled across all sites. Possible remaining variability did not detract from
4
5 the high sensitivity to change of GLOESS, which was developed to be sensitive across
6
7 examiners and machines. Hence, these data suggest that assessment of synovitis by
8
9 GLOESS is a reliable method to address the direct effect of DMARDs on synovitis in
10
11 PsA.
12
13

14
15 The observed improvement in the signs and symptoms of PsA upon exposure to
16
17 secukinumab confirmed its known clinical efficacy and was in accordance with earlier
18
19 studies. Higher ACR responses were observed with secukinumab in the current study
20
21 than in the secukinumab FUTURE 2 and FUTURE 5 studies [19, 20], possibly because
22
23 of the uniquely rigorous combined clinical and ultrasound inclusion criteria on joints, and
24
25 the stringent monitoring in this study over the initial 3 months. Treatment with
26
27 secukinumab was well tolerated and the safety profile was consistent with the
28
29 established safety profile across approved indications.[21]
30
31
32

33
34 In conclusion, ULTIMATE is the first randomised study that evaluated the effect
35
36 of DMARDs on PDUS measured synovitis as the primary endpoint. It demonstrated that
37
38 secukinumab rapidly and significantly decreased synovitis, indicating a direct effect of
39
40 IL-17 inhibition on the synovium in patients with PsA. As synovitis is critical for cartilage
41
42 and bone destruction in PsA [1, 3, 4], these data also provide the basis for the observed
43
44 protection of joint structure by secukinumab in patients with PsA.

Acknowledgments

The authors thank the patients and investigators who participated in the study. The authors also thank John Gallagher (Novartis Pharmaceuticals UK Ltd., UK) and Corine Gaillez (Novartis Pharma AG, Basel, Switzerland) for medical guidance and editorial support. The study was designed by the scientific steering committee and Novartis personnel. The first draft of the manuscript was written by medical writers, employed by the study sponsor (Niladri Maity and Gurleen Kaur, Novartis Healthcare Pvt. Ltd., Hyderabad, India), under the guidance of the authors.

Statistical analyses were performed by statisticians employed by the study sponsor (Novartis Pharma AG, Basel, Switzerland). All authors had access to the data, contributed to the interpretation, and collaborated in the development of the manuscript. All authors critically reviewed and provided feedback on subsequent versions for important intellectual content. All authors approved the final version of the manuscript to be submitted for publication and vouch for the accuracy and completeness of the data and fidelity of this report to the study protocol.

Study conception and design: Maria Antonietta D'Agostino, Georg Schett, Anne-Marie Duggan, Punit Goyanka, Maarten Boers, and Corine Gaillez. **Acquisition of data:** Maria Antonietta D'Agostino, Georg Schett, Alejandra López-Rdz, Ladislav Šenolt, Katalin Fazekas, Ruben Burgos-Vargas, Jose Maldonado-Cocco, Esperanza Naredo, Philippe Carron, and Maarten Boers. **Analysis and interpretation of data:** Maria Antonietta D'Agostino, Georg Schett, Alejandra

12
13 The study (NCT02662985) was supported by Novartis Pharma AG, Basel, Switzerland.
14

15 **Ethics Approval**

16
17 The study protocol was reviewed and approved by the Independent Ethics Committee
18
19 or Institutional Review Board for each participating centre. The study was conducted
20
21 according to the ICH E6 guideline for Good Clinical Practice that has its origin in the
22
23 Declaration of Helsinki. Written informed consent was obtained from all enrolled
24
25 patients.
26
27

28 **Data Sharing Statement**

29
30
31 The datasets generated during and/or analysed during the current study are not
32
33 publicly available. Novartis is committed to sharing with qualified external
34
35 researchers access to patient-level data and supporting clinical documents from
36
37 eligible studies. These requests are reviewed and approved the basis of scientific
38
39 merit. All data provided are anonymized to respect the privacy of patients who have
40
41 participated in the trial, in line with applicable laws and regulations. The data may
42
43 be requested from the corresponding author.
44

Figure legends

Figure 1. Patient disposition through Week 12.

Screen failures are those who were screened but failed to meet the inclusion or met the exclusion criteria or met eligibility but did not move into treatment period 1 (i.e. the patient was not randomised; percentage is computed using the number of screened patients as the denominator).

N, total number of patients

Figure 2. Distribution of synovitis detected by ultrasound and, tender and swollen joints detected by clinical assessment at baseline.

The distribution of synovitis detected by ultrasound and distribution of tender and swollen joint detected by clinical examination at baseline side by side. Frequency of distribution varies from 0 to 80% (highest proportion of patients with ultrasound detected synovitis on wrist) and is visualised by a code of colour from yellow to red shown on the right bar. Grey colour means ultrasound did not assess synovitis of these joints.

CMC, carpometacarpal; DIP, distal interphalangeal; MCP, metacarpophalangeal; MTP, metatarsophalangeal; PIP, proximal interphalangeal

Figure 3. PDUS efficacy outcomes through Week 12.

* $P < 0.05$ versus placebo. (A) primary endpoint GLOESS (MMRM, difference [95% CI]: $-3 [-6; -1]$, $P = 0.004$) at Week 12; (B) GLOESS SH (MMRM, difference [95% CI]: $-3 [-6; -1]$, $P = 0.004$); and (C) GLOESS PD (MMRM, difference [95% CI]: $-2 [-3; -1]$, $P = 0.001$). The 'null zone' presented GLOESS scores was derived from the CI around the difference, which was obtained from the MMRM. It shows the area where the means

Frequency of distribution varies from 0 to 80% (highest proportion of patients with ultrasound detected synovitis on wrist) and is visualised by a code of colour from yellow to red shown on the right bar. Grey colour means ultrasound did not assess synovitis of these joints.

CMC, carpometacarpal; DIP, distal interphalangeal; MCP, metacarpophalangeal; MTP, metatarsophalangeal; PIP, proximal interphalangeal

139x82mm (600 x 600 DPI)

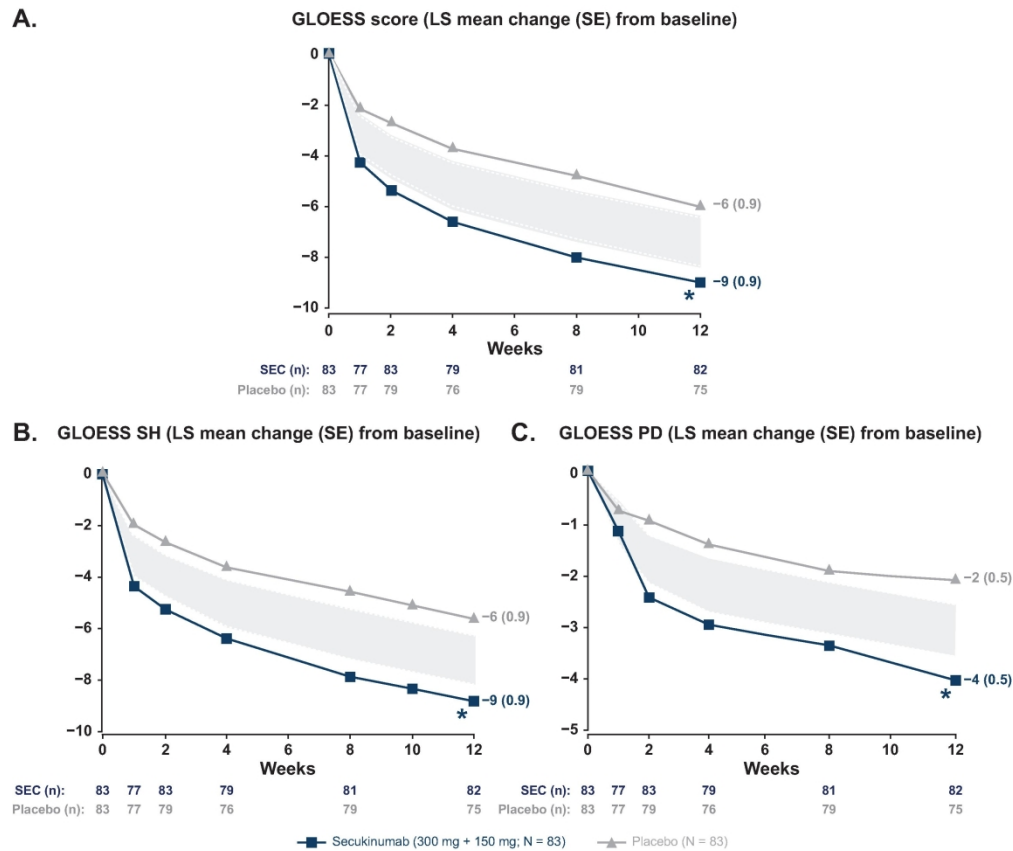

Figure 3. PDUS efficacy outcomes through Week 12.

* $P < 0.05$ versus placebo. (A) primary endpoint GLOESS (MMRM, difference [95% CI]: $-3 [-6; -1]$, $P = 0.004$) at Week 12; (B) GLOESS SH (MMRM, difference [95% CI]: $-3 [-6; -1]$, $P = 0.004$); and (C) GLOESS PD (MMRM, difference [95% CI]: $-2 [-3; -1]$, $P = 0.001$). The 'null zone' presented GLOESS scores was derived from the CI around the difference, which was obtained from the MMRM. It shows the area where the means are located when there is no significant difference between the groups at the $P < 0.05$ level. EULAR, European League Against Rheumatism; GLOESS, Global OMERACT-EULAR Synovitis Score; LS, least squares; MMRM, mixed-effect model repeated measures; N, total number of randomised patients; n, number of evaluable patients; OMERACT, Outcome Measures in Rheumatoid Arthritis Clinical Trials; PD, Power Doppler; SEC, secukinumab; SH, synovial hypertrophy

138x117mm (600 x 600 DPI)

Figure 4. Clinical efficacy outcomes through Week 12.

* $P < 0.05$ versus placebo. (A) ACR20 response (NRI, odds ratio [95% CI]: 5 [2; 9], $P < 0.0001$, relative risk: 2); (B) ACR50 response (NRI, odds ratio [95% CI]: 10 [4; 24], $P < 0.0001$, relative risk: 5); (C) ACR70 response (NRI, odds ratio [95% CI]: 23 [3; 178], $P = 0.0013$, relative risk: 18); and (D) HAQ-DI score (MMRM, difference: -0.5 [-0.6 ; -0.3]; $P < 0.0001$). The 'null zone' presented HAQ-DI score was derived from the CI around the difference, which was obtained from the MMRM. It shows the area where the means are located when there is no significant difference between the groups at the $P < 0.05$ level.

ACR, American College of Rheumatology; HAQ-DI, Health Assessment Questioner Disability Index; LS, least squares; MMRM, mixed-effect model repeated measures; N, total number of randomised patients; NRI, non-responder imputation; n, number of evaluable patients; SEC, secukinumab
